

How to Move WordPress From Local Server to Live Site (2 Methods)

Method 1. Transfer WordPress from Local Server to Live Site Using a Migration Plugin

This method is easier and recommended for beginners. We'll be using a WordPress migration plugin to move WordPress from localhost to a live site.

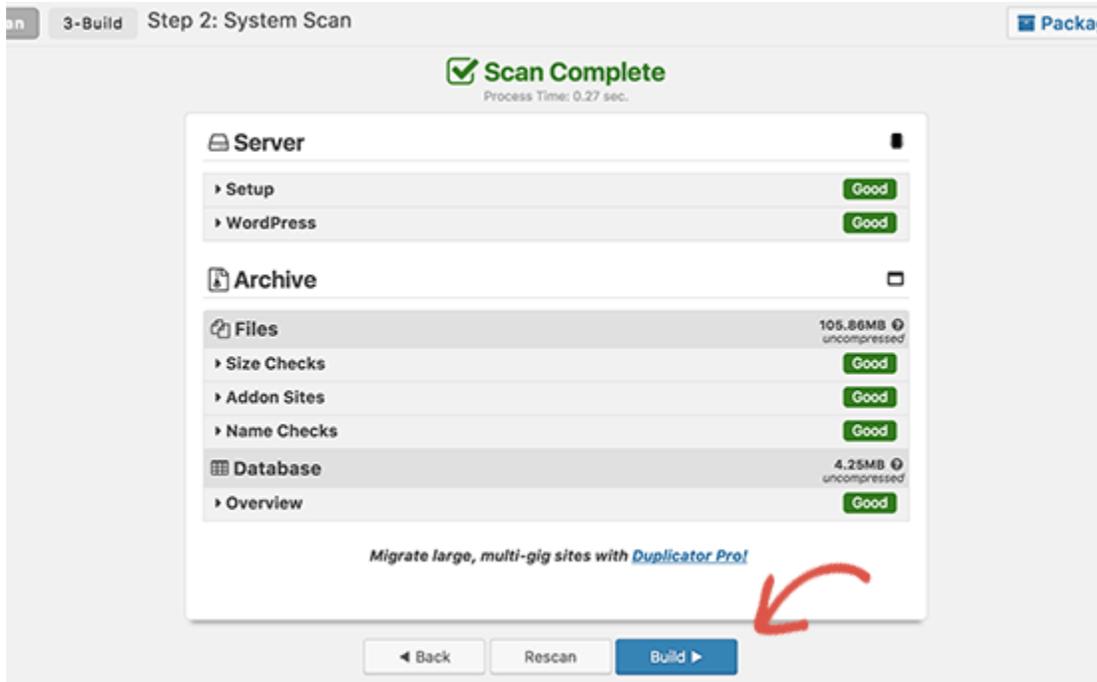

Step 1. Install and Setup Duplicator Plugin

First, thing you need to do is install and activate the **Duplicator** plugin on your local site. Upon activation, you need to go to **Duplicator » Packages** page and click on the 'Create New' button.

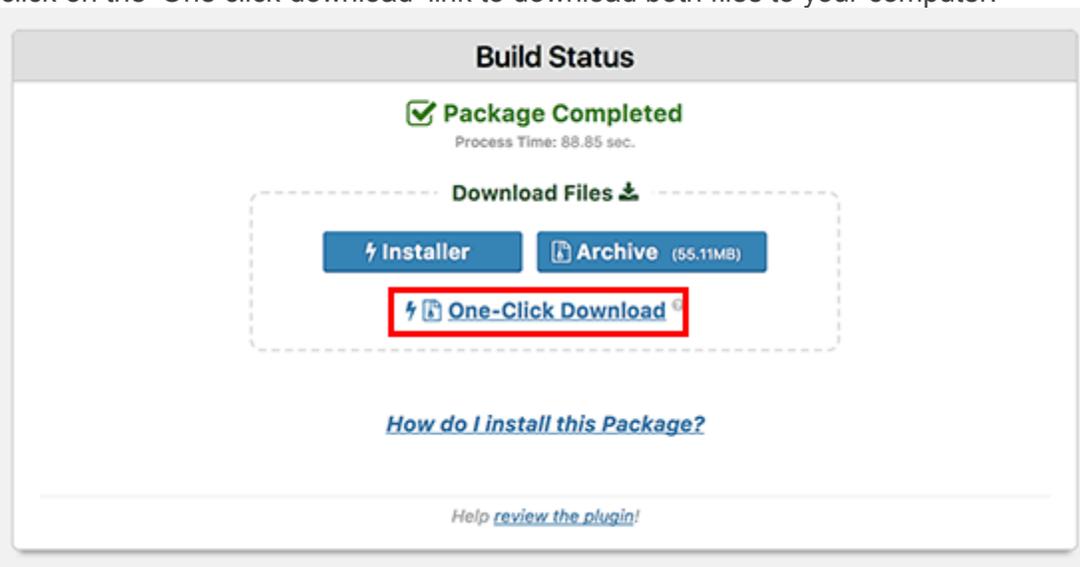

After that, click on the next button to continue.

Duplicator will now run some tests to see if everything is in order. If all items are marked 'Good' then click on the 'Build' button.

This process may take a few minutes depending on the size of your website. You need to leave this tab open until the process is complete.

Once finished, you'll see download options for Installer and the Archive package. You need to click on the 'One click download' link to download both files to your computer.

So what are these files?

Well, the archive file is a copy of your complete WordPress website. It includes all WordPress core files as well as your images, uploads, themes, plugins, and a backup of your WordPress database.

The installer file is a script that will automate the migration by unpacking the archive file.

Step 2. Create a Database for Your Live Site

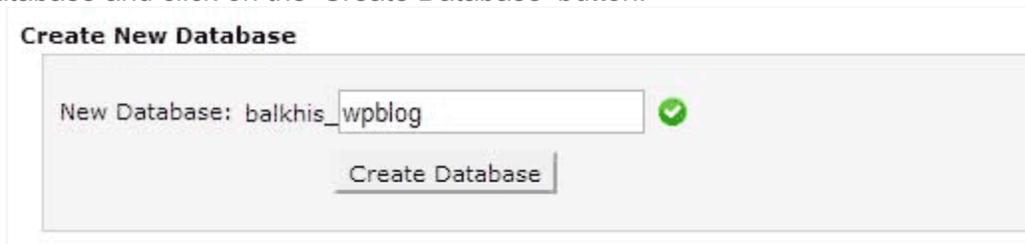

Before you can run the installer or upload the WordPress website from localhost to your hosting server, you will need to create a MySQL database for your live website.

If you have already created a MySQL database, then you can skip this step.

To create a database you need to visit your hosting account's cPanel dashboard. Scroll down to the Databases section and then click on the MySQL Databases icon.

On the next screen, you'll see a field to create a new database. Simply provide a name for your database and click on the 'Create Database' button.

A screenshot of the 'Create New Database' form. The title 'Create New Database' is at the top. Below it is a text input field labeled 'New Database: balkhis_' containing the text 'wpblog'. To the right of the field is a green checkmark icon. Below the field is a 'Create Database' button.

cPanel will now create a new database for you. After that, you need to scroll down to the MySQL Users section.

Next, provide a username and password for your new user and click on the 'Create a user' button.

A screenshot of the 'MySQL Users' section. The title 'MySQL Users' is at the top. Below it is the sub-section 'Add a New User'. There are three input fields: 'Username: wpbeginn_' containing 'wpbeginner', 'Password:,', and 'Password (Again):,'. Each field has a green checkmark icon to its right. Below the password fields is a 'Strength (Why?):' section showing 'Very Strong (100/100)' in a green box and a 'Password Generator' button. At the bottom is a 'Create a User' button.

The new user you just created, still does not have permission to work on the database. Let's change that.

Scroll down to the 'Add User to Database' section. Simply select the database user you created from the dropdown menu next to the 'User' field, then select the database, and click on the add button.

Add a User to a Database

User: wpbeginn_wpbegin

Database: wpbeginn_wplog

Add

Your database is now ready to be used with your WordPress site. Make sure to note down the database name, username, and password. You'll need this information in the next step.

Step 3. Upload Files from Local Server to Live Site

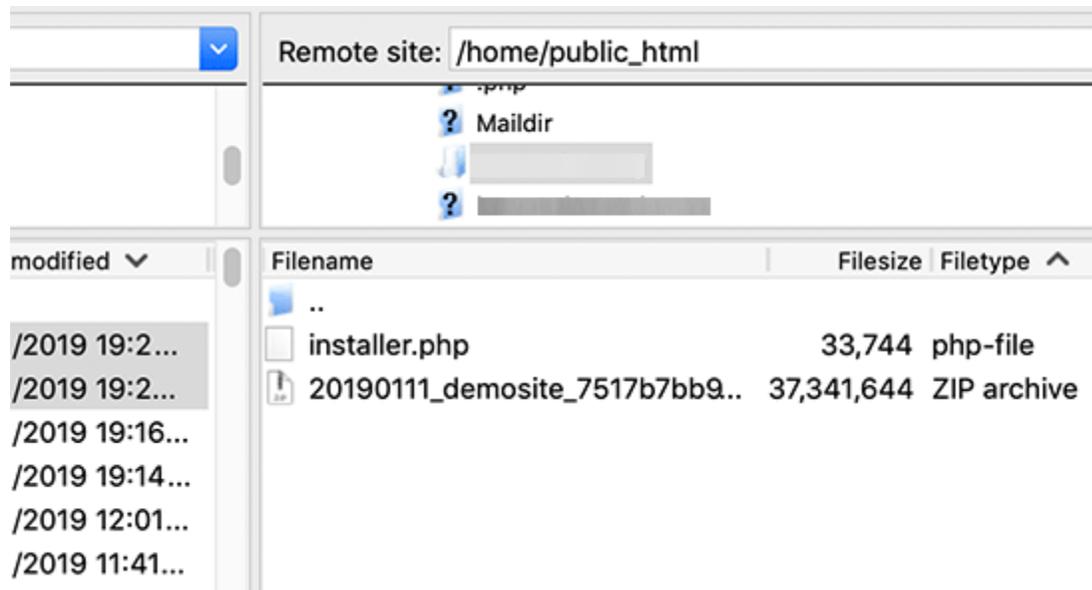

Now you need to upload the archive and installer files from your local site to your hosting account.

First, connect to your live site using an FTP client. Once connected, make sure that the root directory of your website is completely empty.

Normally, root directory is the /home/public_html/ folder.

Some WordPress hosting companies automatically **install WordPress** when you sign up. If you have WordPress files there, then you need to delete them.

After that, you can upload the archive and installer files from Duplicator to your empty root directory.

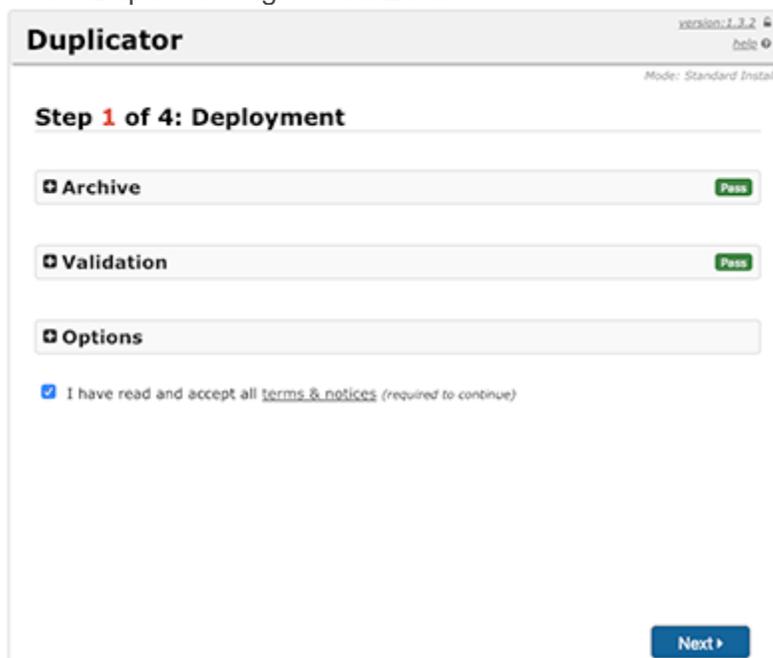

Step 4. Running The Migration Script

After you have uploaded the migration files, you need to visit the following URL in your browser:

<http://example.com/installer.php>

Don't forget to replace example.com with your own domain name.

This will launch the Duplicator migration wizard.

The installer will automatically scan for the archive file and run a validation test. You need to check the terms & conditions checkbox and continue by clicking on the Next button.

On the next screen, it will ask you to enter your WordPress database information.

Your host will likely be localhost. After that, you will enter the details of the database you created in the earlier step.

Duplicator version: 1.2.30
» info » help

Step 2 of 4: Install Database

[installer-log.txt](#)

Basic cPanel

Setup

Action: Connect and Remove All Data

Host: localhost Port: 3306

Database: wpblog
Warning: The selected 'Action' above will remove all data from this database!

User: wpbeginner

Password: MySQLUserPasswordHere

Options

Test Database Next

Click on the next button to continue.

Duplicator will now import your WordPress database backup from the archive into your new database.

Next, it will ask you to update site URL or Path. You shouldn't have to change anything since it automatically detects the URL of your live website, and its path.

Duplicator version: 1.3.2
help

Mode: Standard Install

Step 3 of 4: Update Data

[dyc-installer-log.txt](#)

New Settings

URL: http://example.com 985

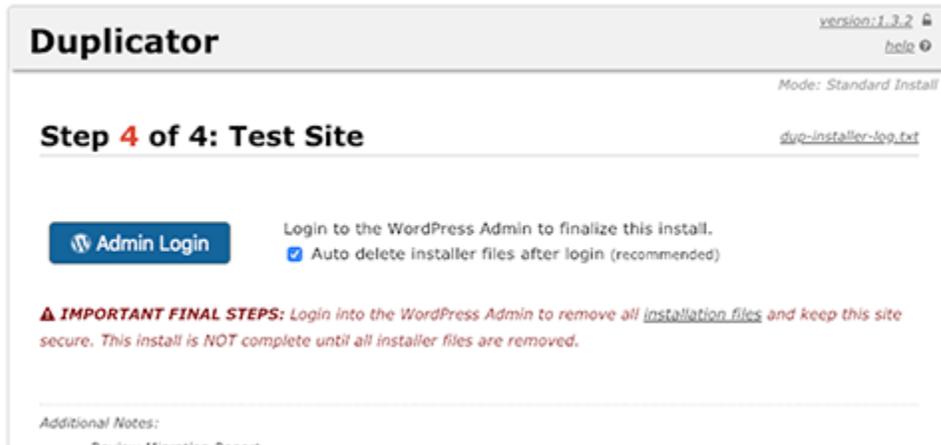

Path: /home/public_html/

Title: Demo Site

Replace

Click on the next button to continue.

Duplicator will now finish the migration and will show you a success screen. You can now click on the 'Admin Login' button to enter the WordPress admin area of your live site.

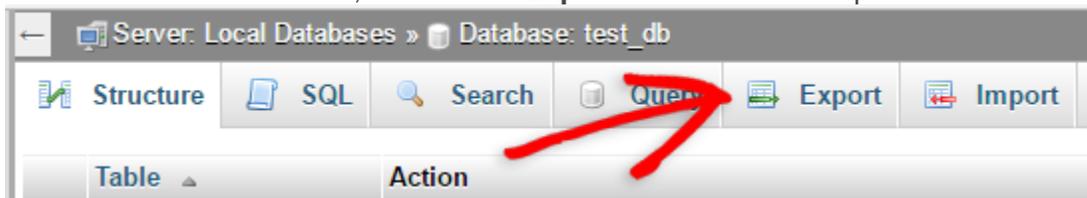

Once you login to your live site, Duplicator will automatically clean up the installation files. That's all, you have successfully moved WordPress from local server to your live site.

Method 2. Manually Transfer WordPress from Local Server to Live Site

In this method, we will show you how to manually move WordPress from local server to your live site. It will come in handy if the first method doesn't work or you prefer to do it manually.

Step 1: Export Local WordPress Database

The first thing you need to do is export your local WordPress database. We'll be using phpMyAdmin to do that. Simply go to <http://localhost/phpmyadmin/> and click on your WordPress database. Next, click on the **Export** button from the top menu bar.

In the **Export Method** option, you can choose "Quick" or "Custom". Custom will provide you with more options to export your database.

We recommend choosing Quick, and then click the **Go** button to download your database.

Exporting tables from "test_db" database

Export method:

- Quick - display only the minimal options
- Custom - display all possible options

Format:

SQL ▼

Go

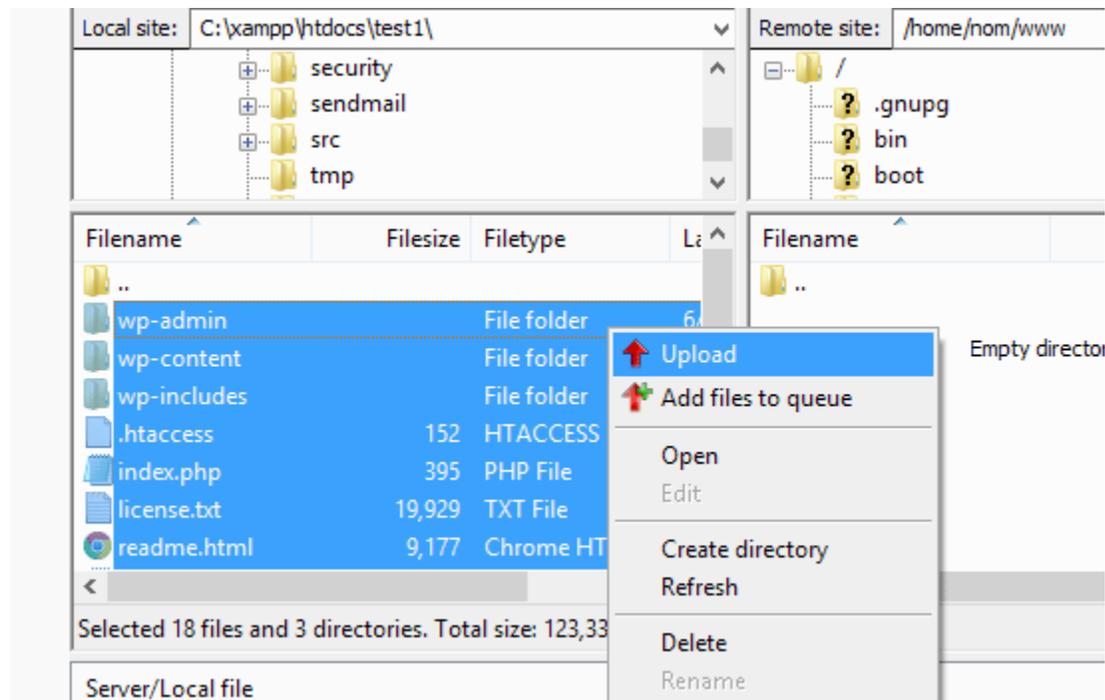

Step 2: Upload WordPress Files to Live Site

Now we'll need to move all your website files to the live site.

To get started, go ahead and open your FTP client and connect to your web hosting account.

Once you're connected to your live site, make sure you upload the files in the right directory. For example, if you want the site to be hosted on `yoursite.com`, then you would want to upload all the files in your `public_html` directory.

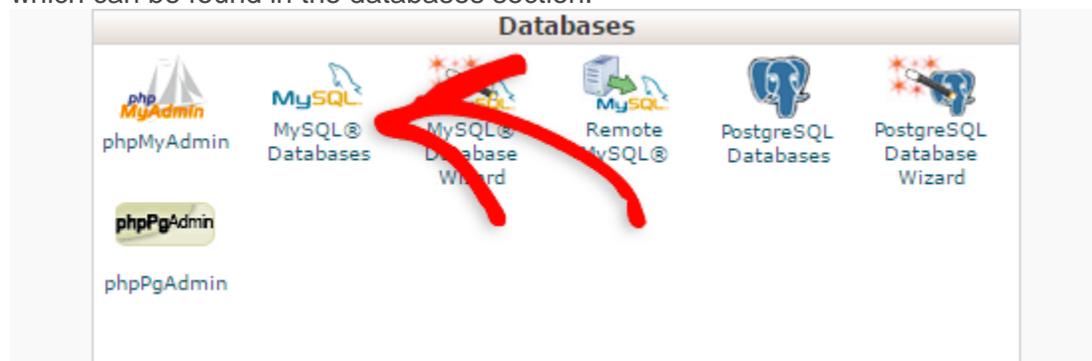

Now select your local WordPress files and upload them to your live server.

Step 3: Create MySQL Database on Live Site

While your FTP client is uploading your WordPress files, you can start importing your database to the live server. Most **WordPress hosting** providers offer cPanel to manage your hosting account, so we'll show you how to create a database using cPanel.

First, you need to log in to your cPanel dashboard and click on the **MySQL Databases** icon which can be found in the databases section.

On the next screen, create a database by entering a name for your database and clicking the **Create Database** button.

Create New Database

New Database: x3demob_

After creating your database, scroll down to the **MySQL Users** section and create or add an existing user to the database.

After adding the user, cPanel will take you to set MySQL privileges for that user. Simply grant all privileges to the user by making sure every box is checked, and then click the **Make Changes** button.

<input checked="" type="checkbox"/> ALL PRIVILEGES	
<input checked="" type="checkbox"/> ALTER	<input checked="" type="checkbox"/> ALTER ROUTINE
<input checked="" type="checkbox"/> CREATE	<input checked="" type="checkbox"/> CREATE ROUTINE
<input checked="" type="checkbox"/> CREATE TEMPORARY TABLES	<input checked="" type="checkbox"/> CREATE VIEW
<input checked="" type="checkbox"/> DELETE	<input checked="" type="checkbox"/> DROP
<input checked="" type="checkbox"/> EVENT	<input checked="" type="checkbox"/> EXECUTE
<input checked="" type="checkbox"/> INDEX	<input checked="" type="checkbox"/> INSERT
<input checked="" type="checkbox"/> LOCK TABLES	<input checked="" type="checkbox"/> REFERENCES
<input checked="" type="checkbox"/> SELECT	<input checked="" type="checkbox"/> SHOW VIEW
<input checked="" type="checkbox"/> TRIGGER	<input checked="" type="checkbox"/> UPDATE

Step 4: Import WordPress Database on Live Site

The next step in the process is to import your WordPress database.

Go to your cPanel dashboard, scroll down to the databases section and click on **phpMyAdmin**.

This will take you to phpMyAdmin where you want to click on the database you created in Step 3. PhpMyAdmin will show your new database with no tables.

Click on the **Import** tab in the top menu. On the import page, click on **Choose File** button and then select the database file you saved in Step 1.

Lastly, press the **Go** button at the bottom of the page. PhpMyadmin will now import your WordPress database.

Structure SQL Search Query Export **Import**

Importing into the database "test_db"

File to import:

File may be compressed (gzip, bzip2, zip) or uncompressed.
A compressed file's name must end in `.[format].[compression]`. Example: `.sql.zip`

Browse your computer: file chosen (Max: 128MiB)

You may also drag and drop a file on any page.

Character set of the file:

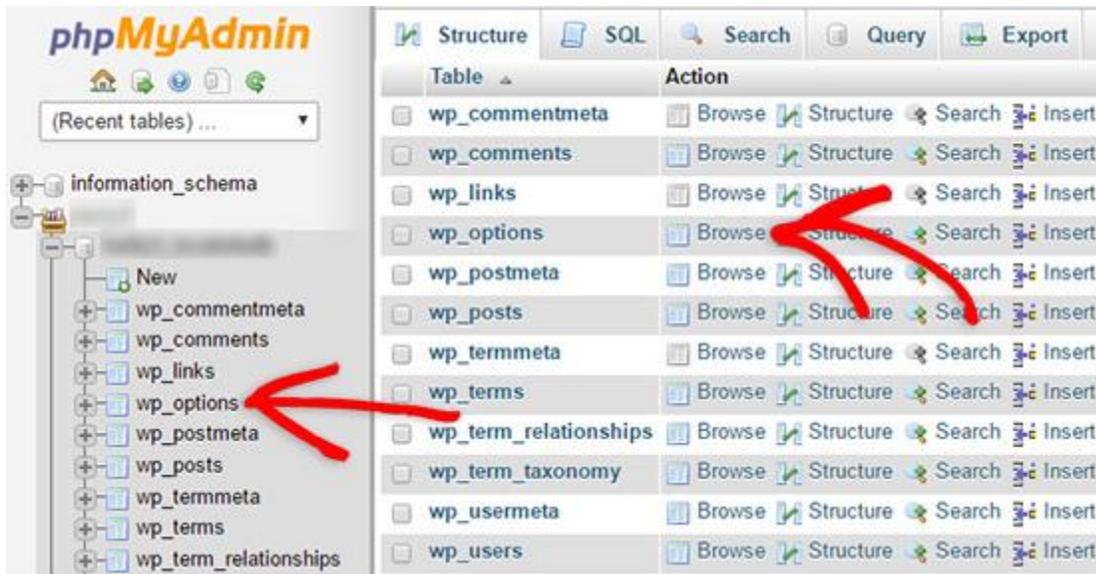

Step 5: Change the Site URL

Now you need to change the site URL in your database, so that it will connect with your live WordPress site.

In phpMyAdmin, look for the `wp_options` table in your database that we just imported in step 4.

If you **changed your database prefix**, then instead of `wp_options` it might be `{prefix}_options`.

Click on the **Browse** button next to `wp_options` or the link that you see in the sidebar to open the page with a list of fields within the `wp_options` table. See screenshot below:

Under the field **options_name**, you need to look for **siteurl**. Click the Edit Field icon which can be found at the far left at the beginning of the row.

+ Options		option_id	option_name	option_value
<input type="checkbox"/>	Edit Copy Delete	1	siteurl	http://
<input type="checkbox"/>	Edit Copy Delete	2	home	http://
<input type="checkbox"/>	Edit Copy Delete	3	blogname	Test Website

When you click the edit field, an edit field window will appear. In the input box for option_value, you will see the URL of your local install probably something like: `http://localhost/test`. Carefully insert your new site url in this field, for example: `https://www.wpbeginner.com`. Save the field by clicking the **Go** button.

Column	Type	Function	Null	Value
option_id	bigint(20) unsigned			1
option_name	varchar(191)			siteurl
option_value	longtext			http://www.wpbeginner.com
autoload	varchar(20)			yes

Save and then Go back to previous page

Go Reset

Next, you need to replicate this step for the option name: **home**. The wp_options page can be a few pages long, so simply find the home tab.

Usually it is on the second page which you can navigate to by clicking on the pagination arrows in phpMyAdmin.

Update the **home** url to be the same as your **siteurl**.

Step 6: Setup Your Live Site

Now that we have imported the database and all of our content should be uploaded, it's time to configure WordPress.

At this time, your site should be showing an **Error Establishing Database Connection** error.

To fix this, connect to your website using an FTP client and edit wp-config.php file.

You will need to provide the database name, user and password you created earlier in Step 3.

Next, save the wp-config.php file and upload it back to your server.

You can now visit your website, and it should be live now.

Next, you need to login to your WordPress admin panel and go to **Settings » General**. Without changing anything, scroll to the bottom and click the **Save Changes** button.

This will ensure that the site URL is corrected anywhere else that it needs to be.

After that go to **Settings » Permalink** and click **Save Changes** to ensure that all post links are working fine.

Step 7: Fix Images and Broken Links by Updating Paths

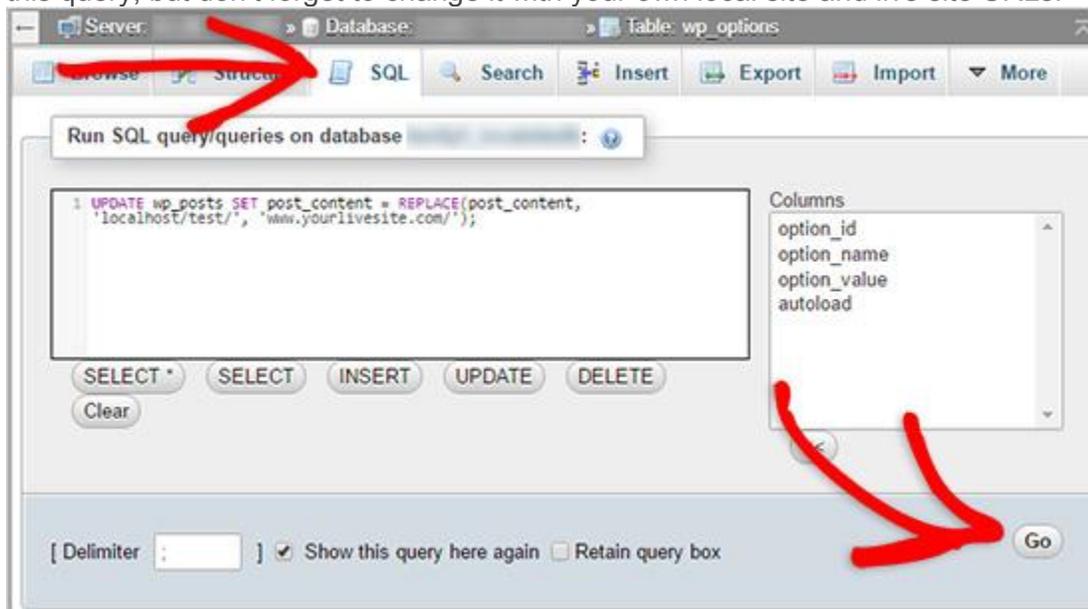

Whenever you are moving a **WordPress site from one domain to another**, or from local server to a live site, you'll face broken links and missing images.

You can either use the SQL query or use the **Velvet Blues WordPress plugin**.

For those who want to do it via SQL, here is a simple SQL query that should solve this problem:

```
1 UPDATE wp_posts SET post_content = REPLACE(post_content,  
1 'localhost/test/', 'www.yourlivesite.com/');
```

Simply go to phpMyAdmin, click on your database and then click on SQL from top menu. Write this query, but don't forget to change it with your own local site and live site URLs.

That's all, you have successfully migrated WordPress from localserver to a live site!
